

BATCH : B107 AWS-DevOps
LESSON : **Kubernetes**
DATE : 22.05.2023
SUBJECT : **Networking**

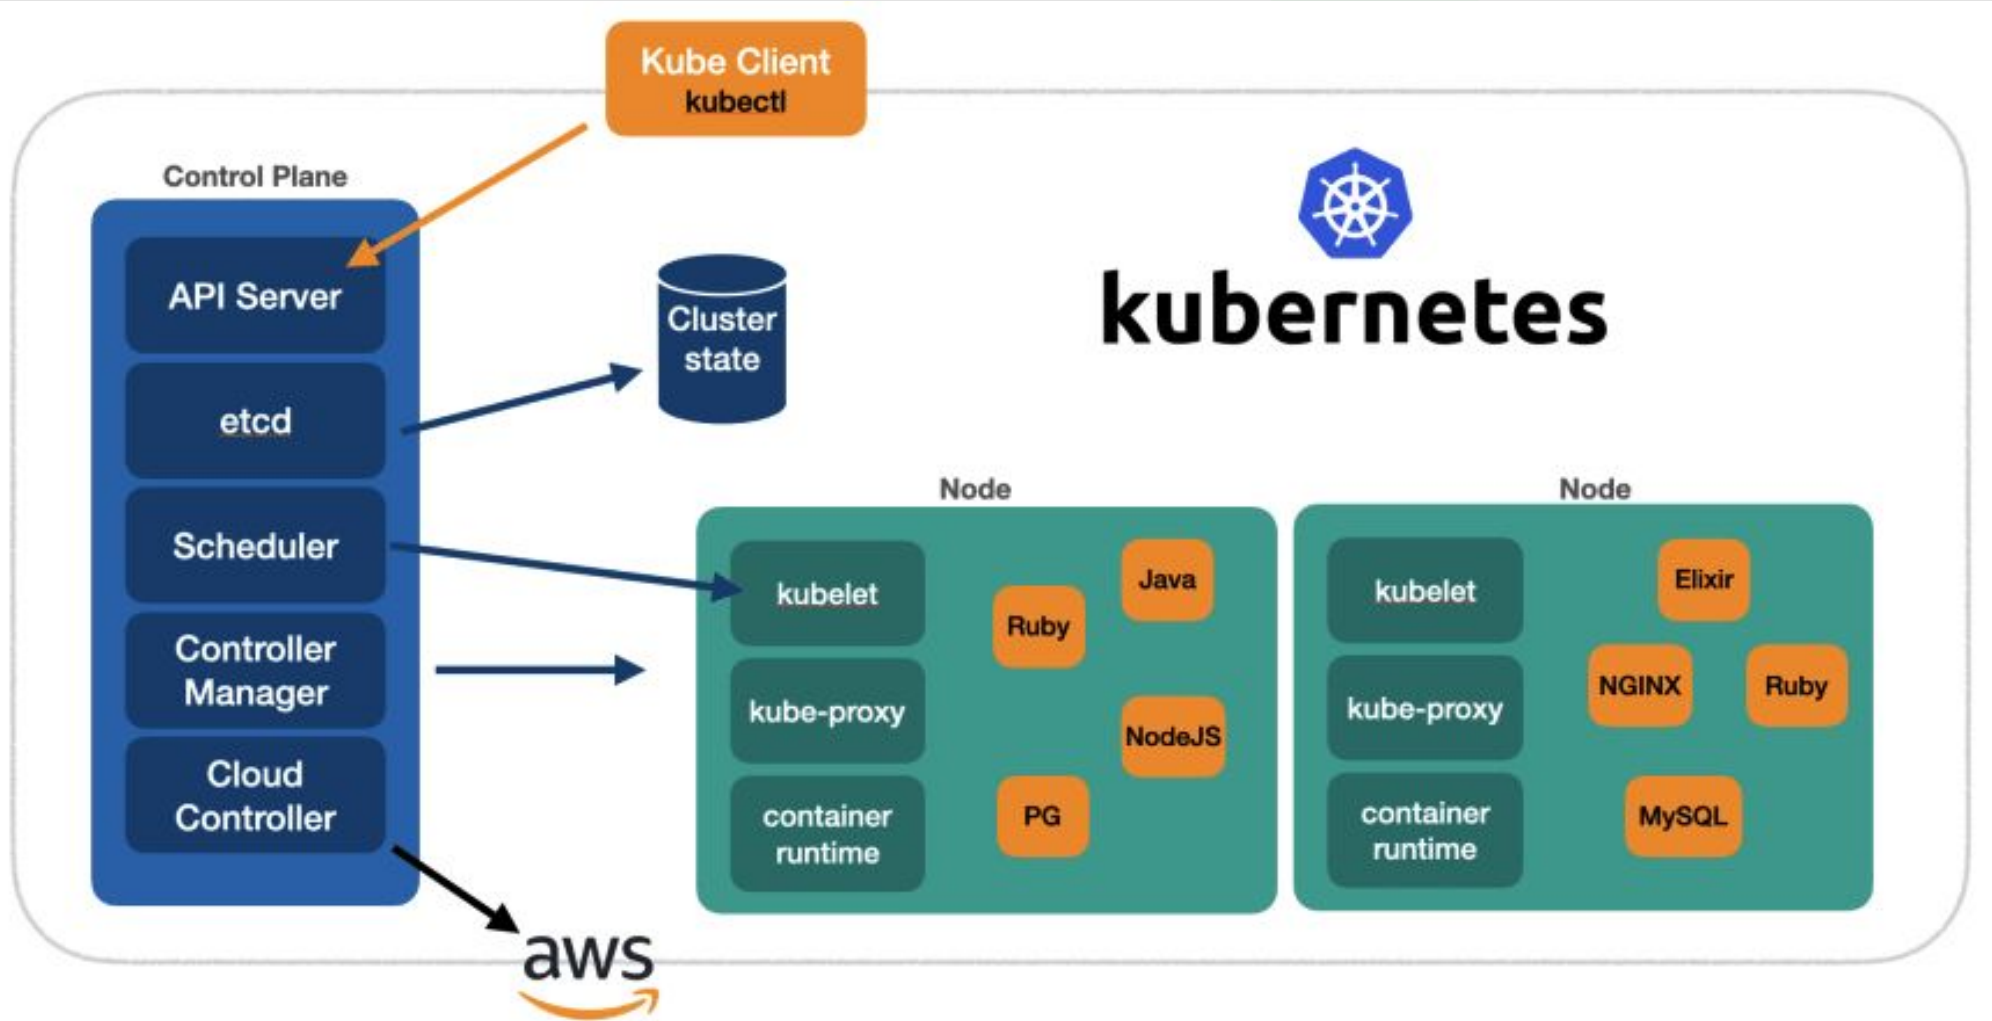

ZOOM GİRİŞLERİNİZİ LÜTFEN **LMS** SİSTEMİ ÜZERİNDEN YAPINIZ

Kubernetes

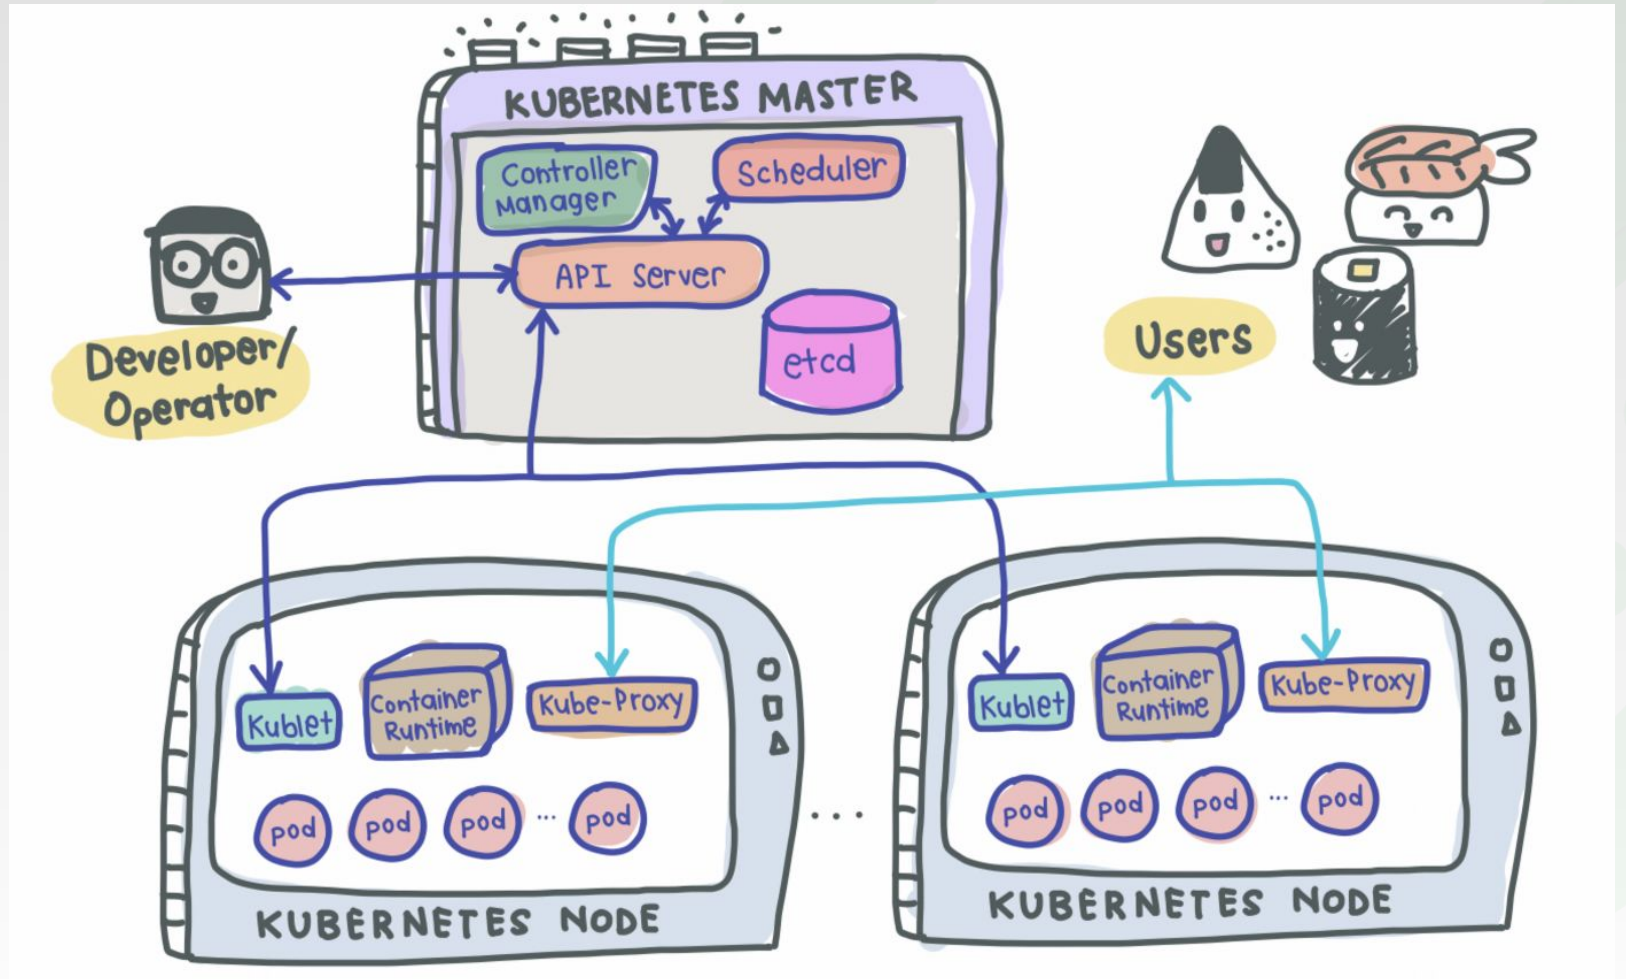

Review

In a K8s cluster:

- I need to start a containerized app. Solution: use .. Pod
- I need to launch a containerized app of 10 replicas. Solution: use .. ReplicaSet
- I need to configure updates on a containerized app. Solution: use .. Deployment
- I need to make sure a specific group of Pods are run on a specific node. Labels, Selectors
- I need to separate resources of Java Dev from the rest of the team. Namespaces

Cluster Networking

Cluster Networking

There are 4 distinct networking problems to address:

- ◆ Container-to-container communications:
- ◆ Pod-to-Pod communications:
- ◆ Pod-to-Service communications: this is covered by services.
- ◆ External-to-Service communications: this is covered by services.

Cluster Networking

- Container to Container
Using “localhost:port”

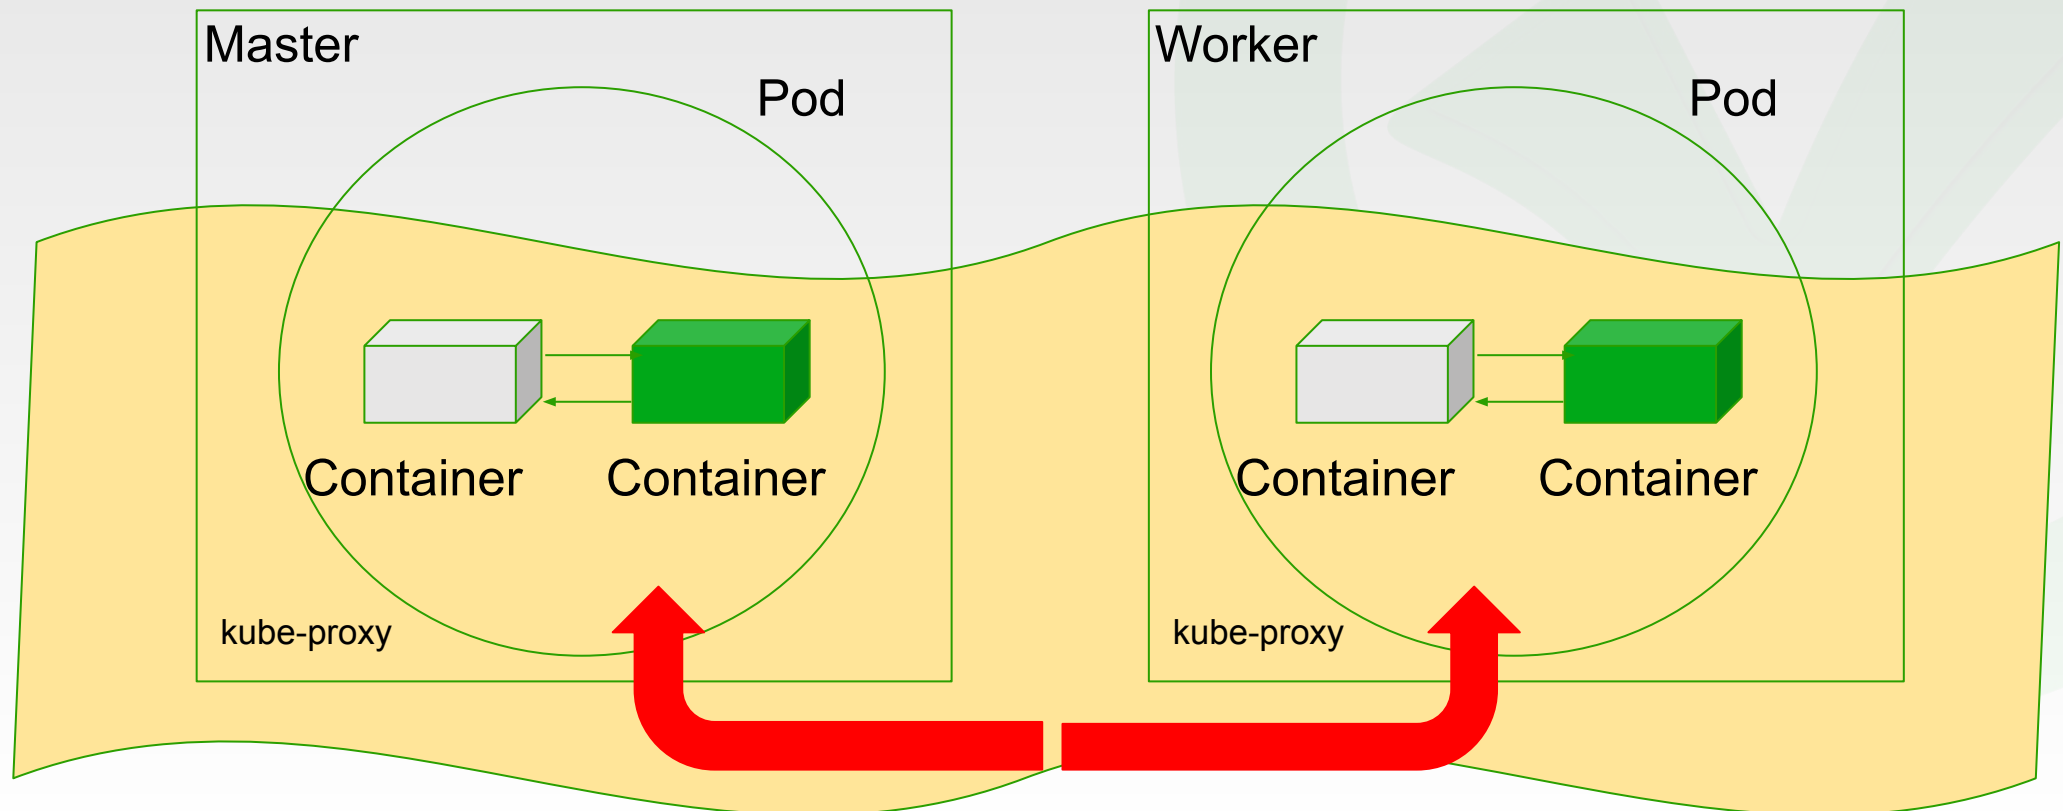

Cluster Networking

- Pod to Pod

Using networking plugins

Cluster Networking

- Pod to Pod
 - Using networking plugins
- CNI (Container Network Interface)

It is a framework for dynamically configuring networking resources.

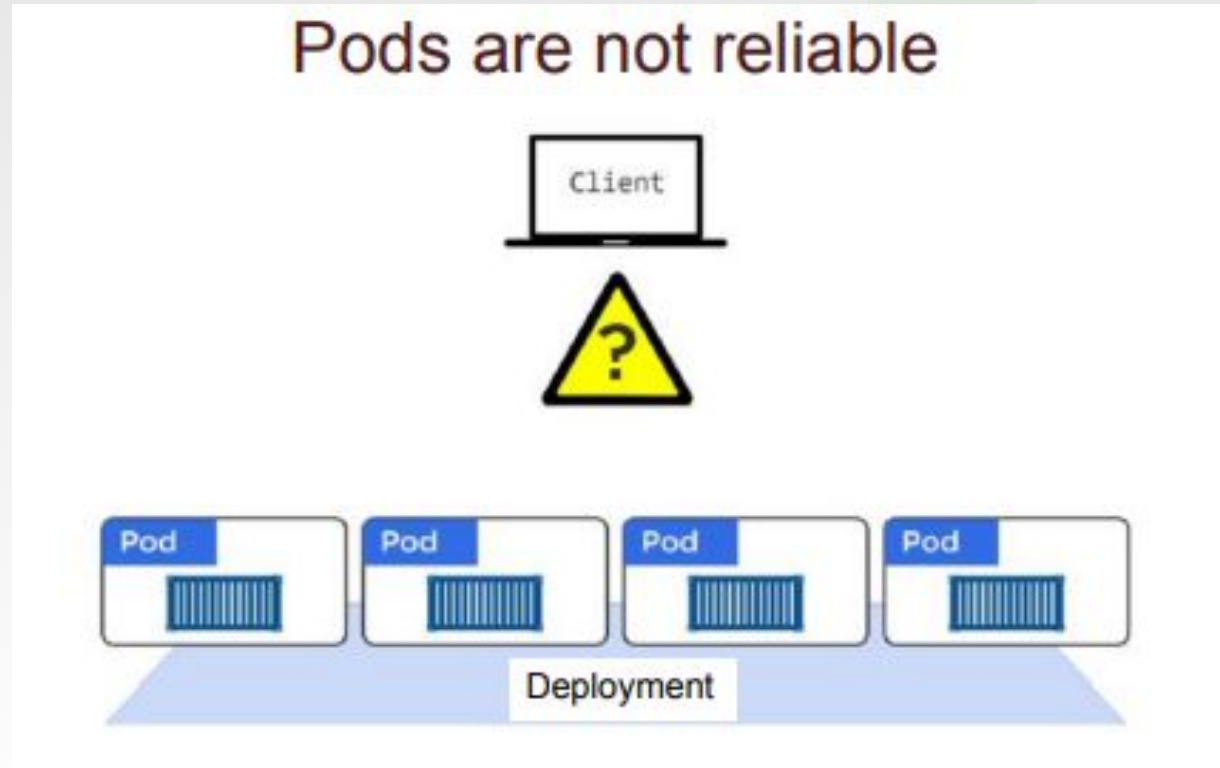

Some common plugins: Calico, Flannel

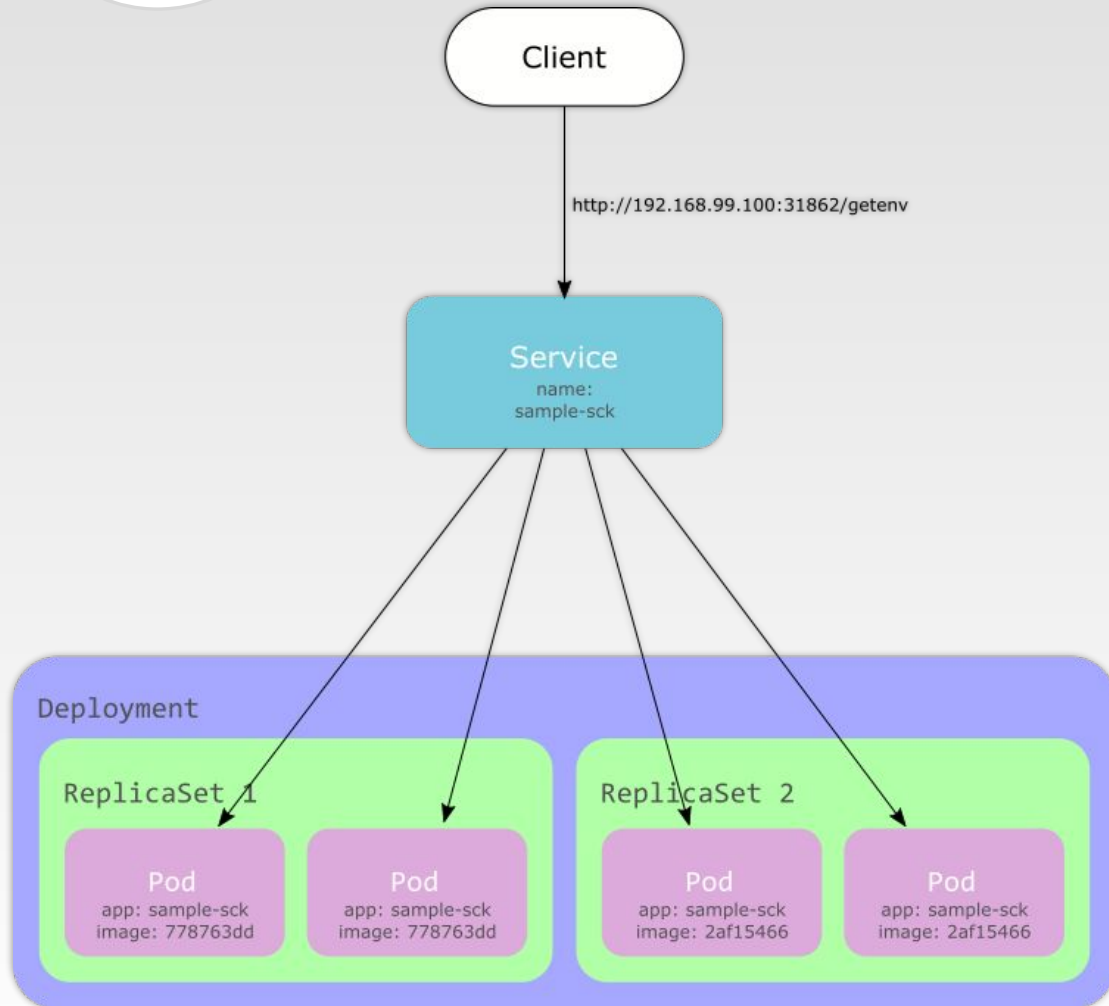

Services

Thanks to plugins, pods can communicate over IP addresses, however ..

Services

- A Service offers a single DNS entry for a containerized application managed by the Kubernetes cluster.
- The Service is associated with the Pods, and provides them with a **stable IP**, DNS and port. It also **load-balances** requests across the Pods.
- Service **logically groups Pods** and defines a policy to access them. This grouping is achieved via **Labels and Selectors**.

Services

Kubernetes Service

A service allows you to dynamically access a group of replica pods.

- Kubernetes Services enable communication between various components within and outside of the application.
- Kubernetes Services help us connect applications together with other applications or users.

kube-proxy

Each cluster node runs a daemon called kube-proxy

- kube-proxy is responsible for implementing the Service **configuration** on behalf of an administrator or developer
- For each new Service, on each node, kube-proxy configures **iptables rules** to capture the traffic for its ClusterIP and forwards it to one of the Service's endpoints.
- When the Service is removed, kube-proxy removes the corresponding iptables rules on all nodes as well.
- If **kube-proxy fails** the node goes into **Not Ready** state

Service Discovery

- Kubernetes has an **add-on for DNS**, which creates a DNS record for each Service and its format is

- Services within the same Namespace **find other Services just by their names.**
- If we add a Service redis-master in my-ns Namespace, all Pods in the same my-ns Namespace lookup the Service just by its name, ex. redis-master.

my-ns

test-ns

To connect to the "Game pod" and "db pod":

From "web pod" -> "Game pod" --> hostname: game-sevice.my-ns:port
game-service:port

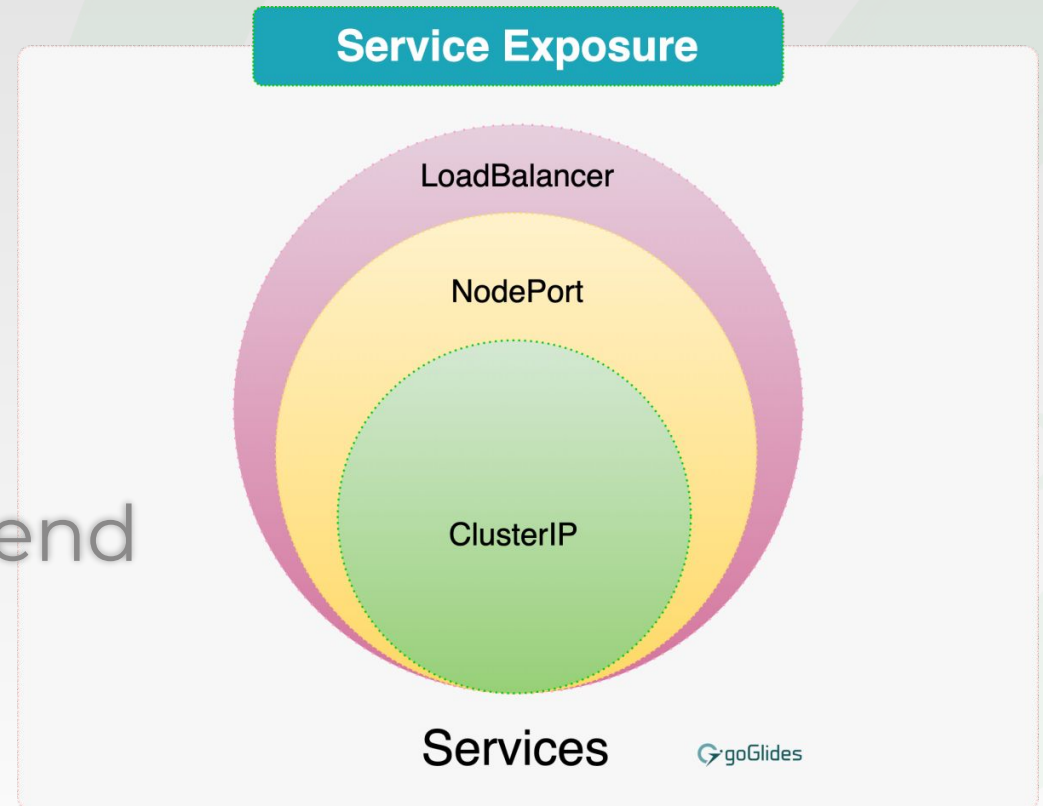

From "web pod" -> "db pod" --> hostname: db-service.test-ns.svc.cluster.local:port

Service Types

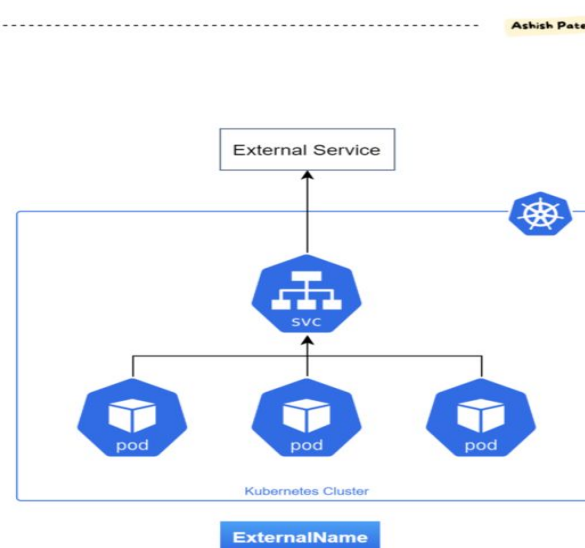

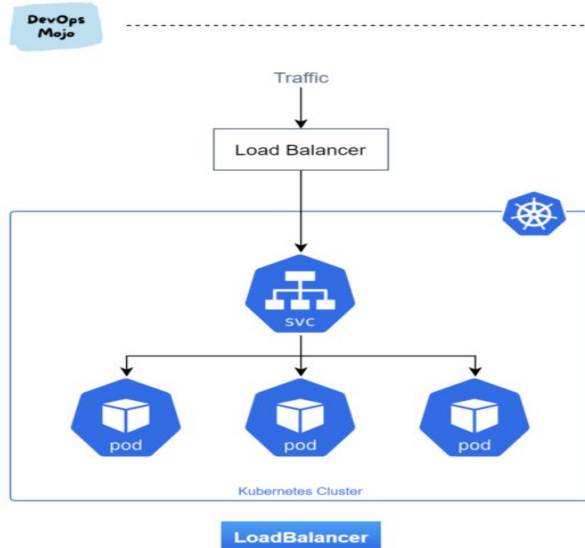

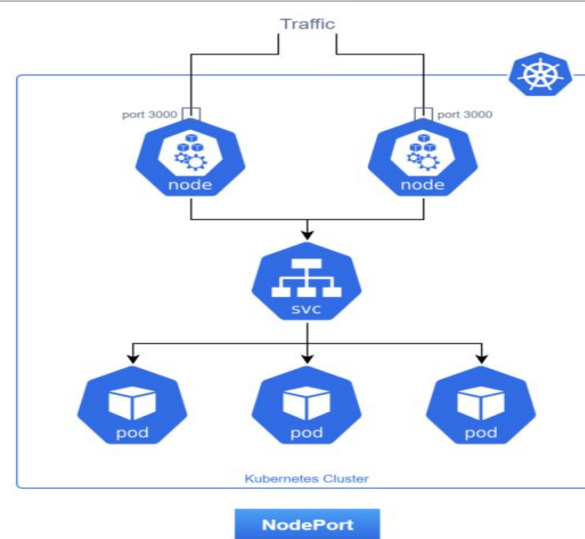

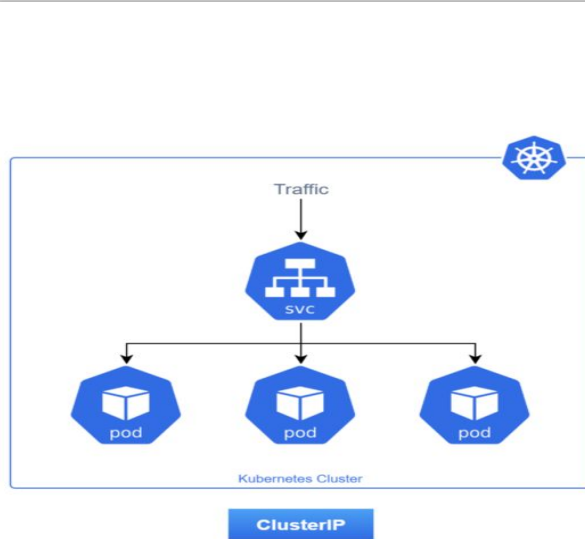

There are 4 major service types:

- ClusterIP (default)
 - **Network inside cluster**
- NodePort
 - **Network coming from**
 - Internet, usually for Frontend
- LoadBalancer
 - **Used by cloud provider**
- ExternalName

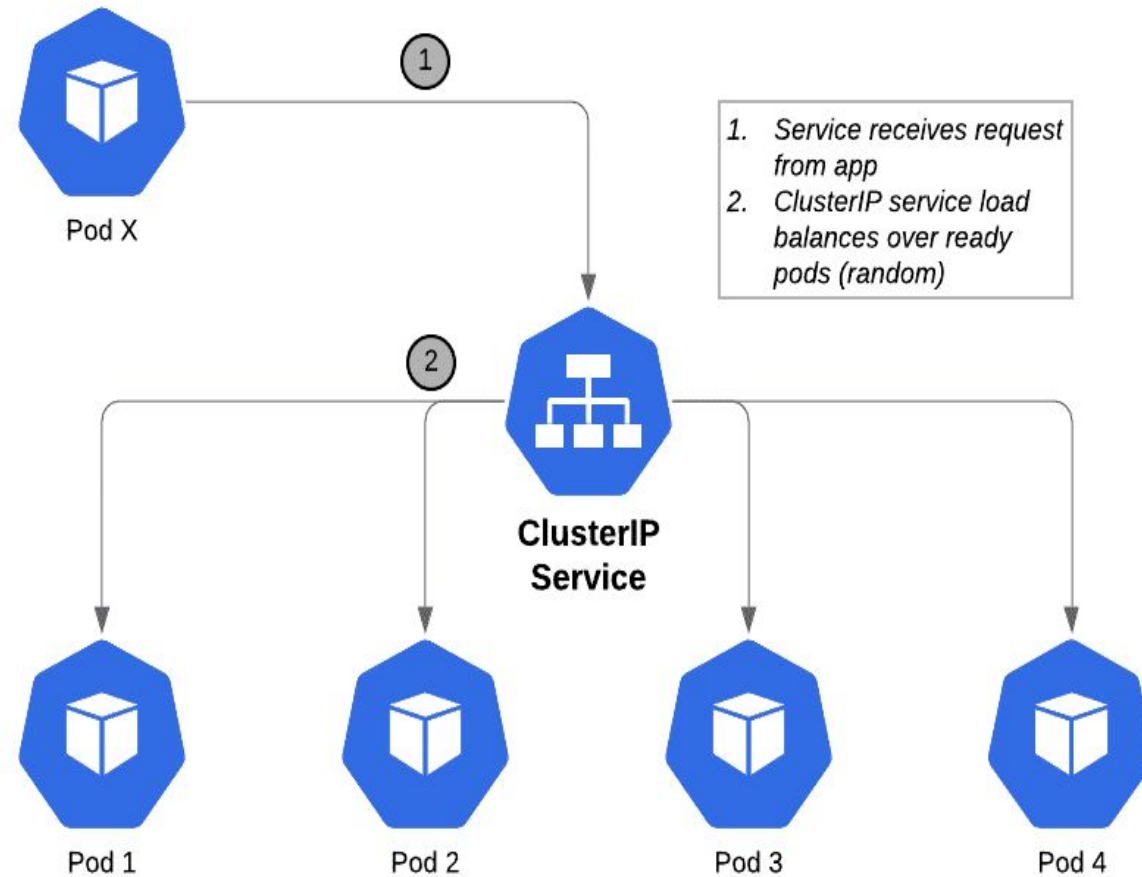

Service Types

Services

Kubernetes Cluster

ClusterIP Service

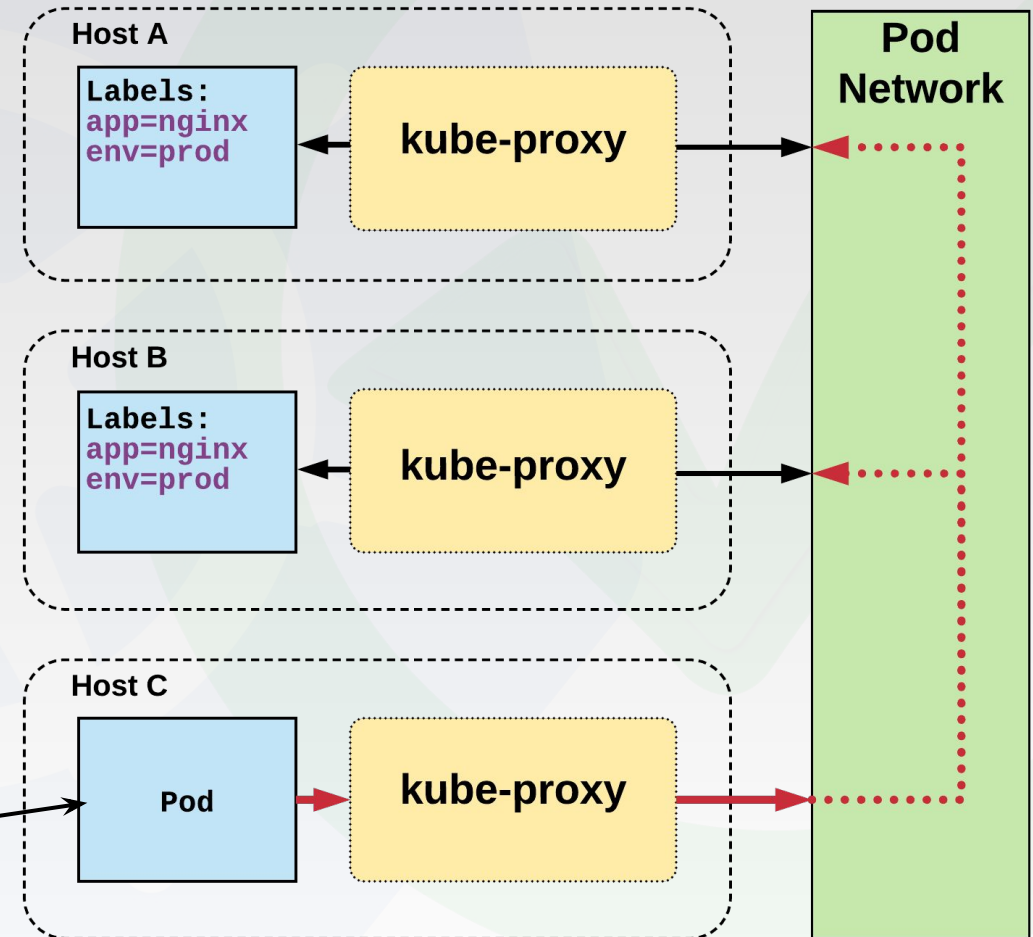

```
apiVersion: v1
kind: Service
metadata:
  name: example-prod
spec:
  selector:
    app: nginx
    env: prod
  ports:
  - protocol: TCP
    port: 80
    targetPort: 80
```

→ **ClusterIP service exposes a service on a strictly cluster internal virtual IP.**

Cluster IP Service

Name: example-prod
Selector: app=nginx,env=prod
Type: ClusterIP
IP: 10.96.28.176
Port: <unset> 80/TCP
TargetPort: 80/TCP
Endpoints: 10.255.16.3:80,
10.255.16.4:80

```
/ # nslookup example-prod.default.svc.cluster.local  
Name:      example-prod.default.svc.cluster.local  
Address 1: 10.96.28.176  
example-prod.default.svc.cluster.local
```

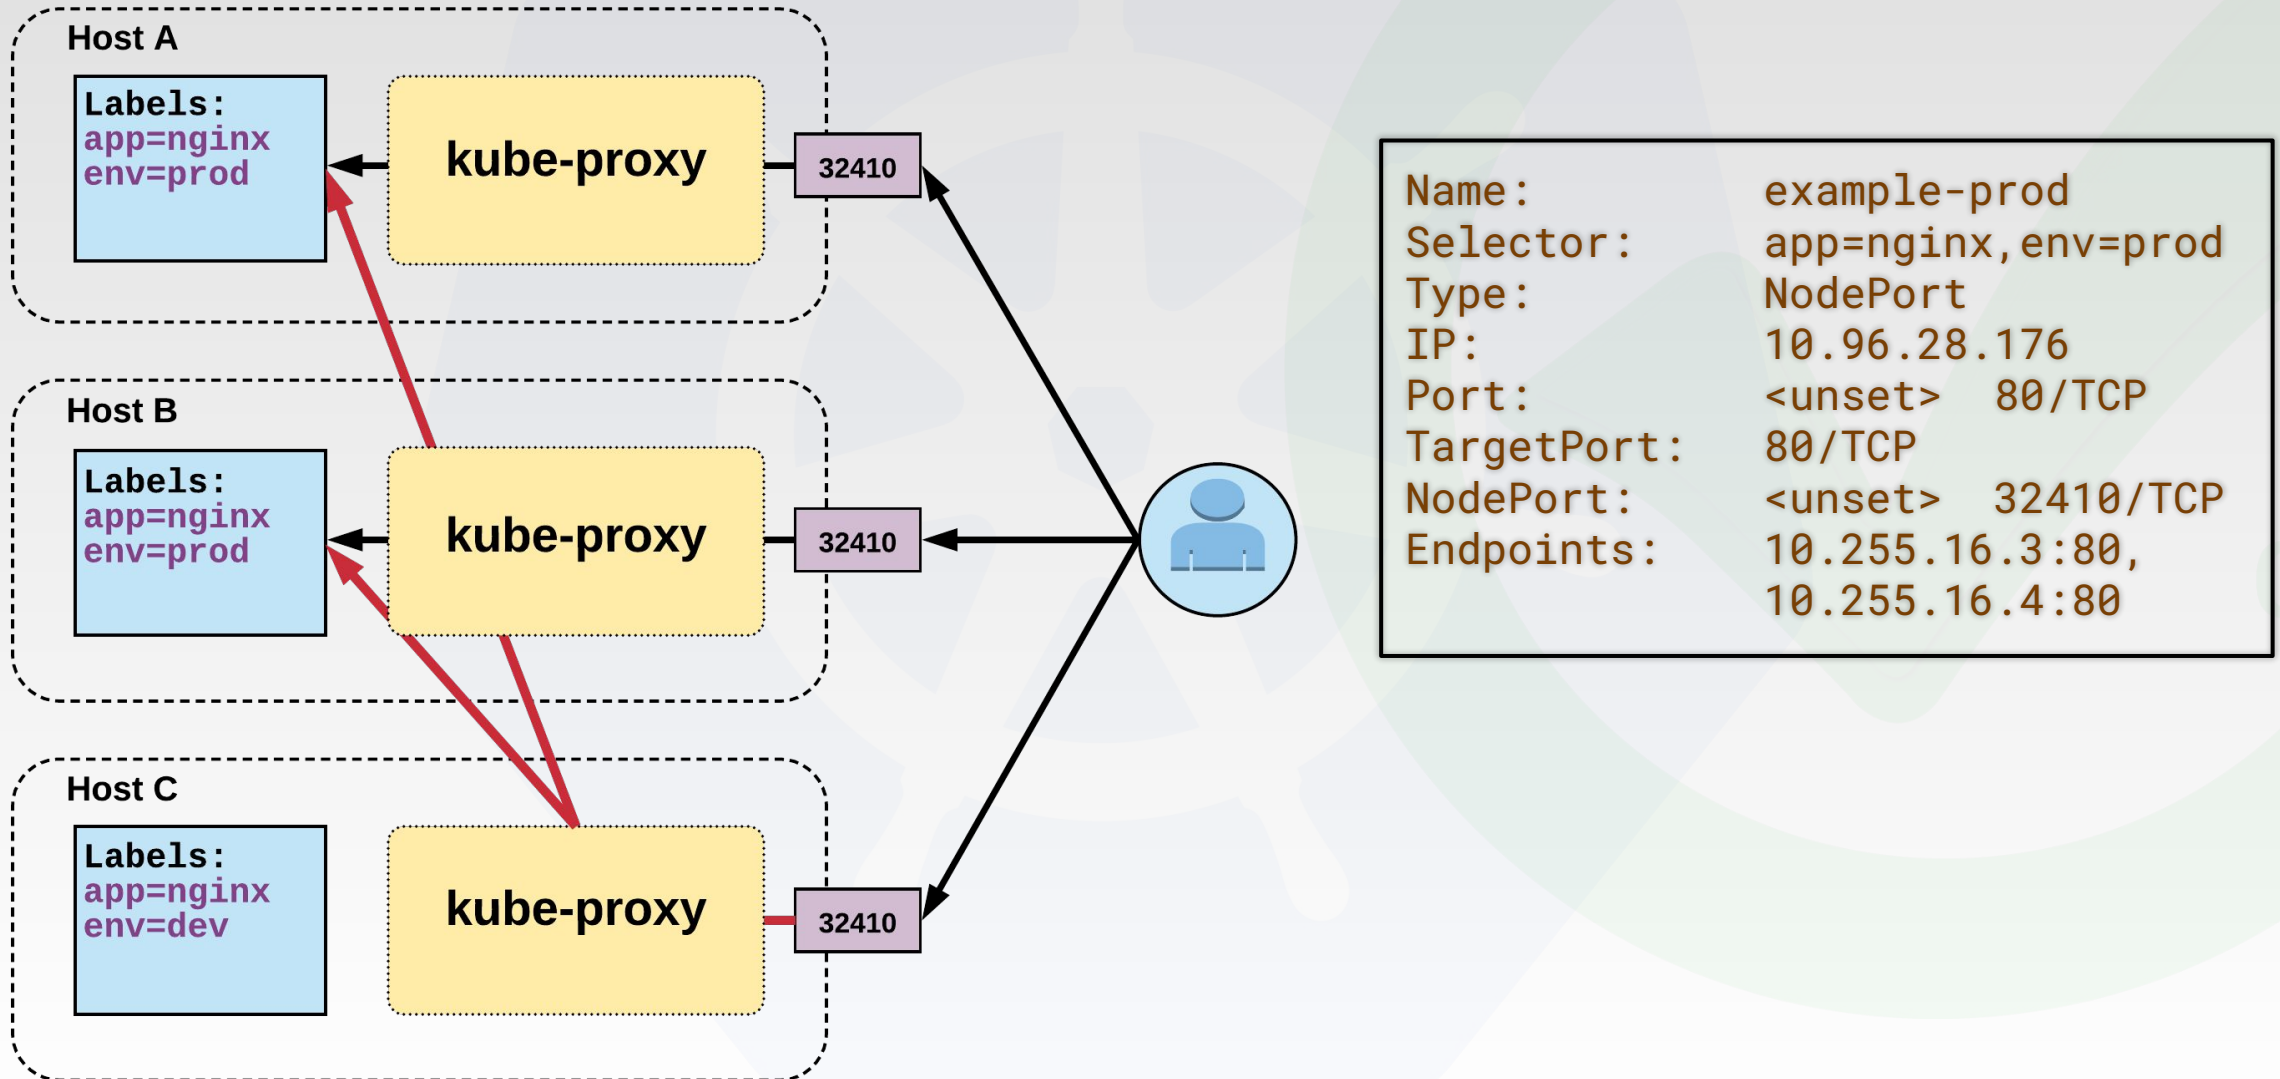

NodePort Service

```
apiVersion: v1
kind: Service
metadata:
  name: example-prod
spec:
  type: NodePort
  selector:
    app: nginx
    env: prod
  ports:
    - nodePort: 32410
      protocol: TCP
      port: 80
      targetPort: 80
```

- NodePort services extend the ClusterIP service.
- Exposes a port on every node's IP.
- Port can either be statically defined, or dynamically taken from a range between 30000-32767.

NodePort Service

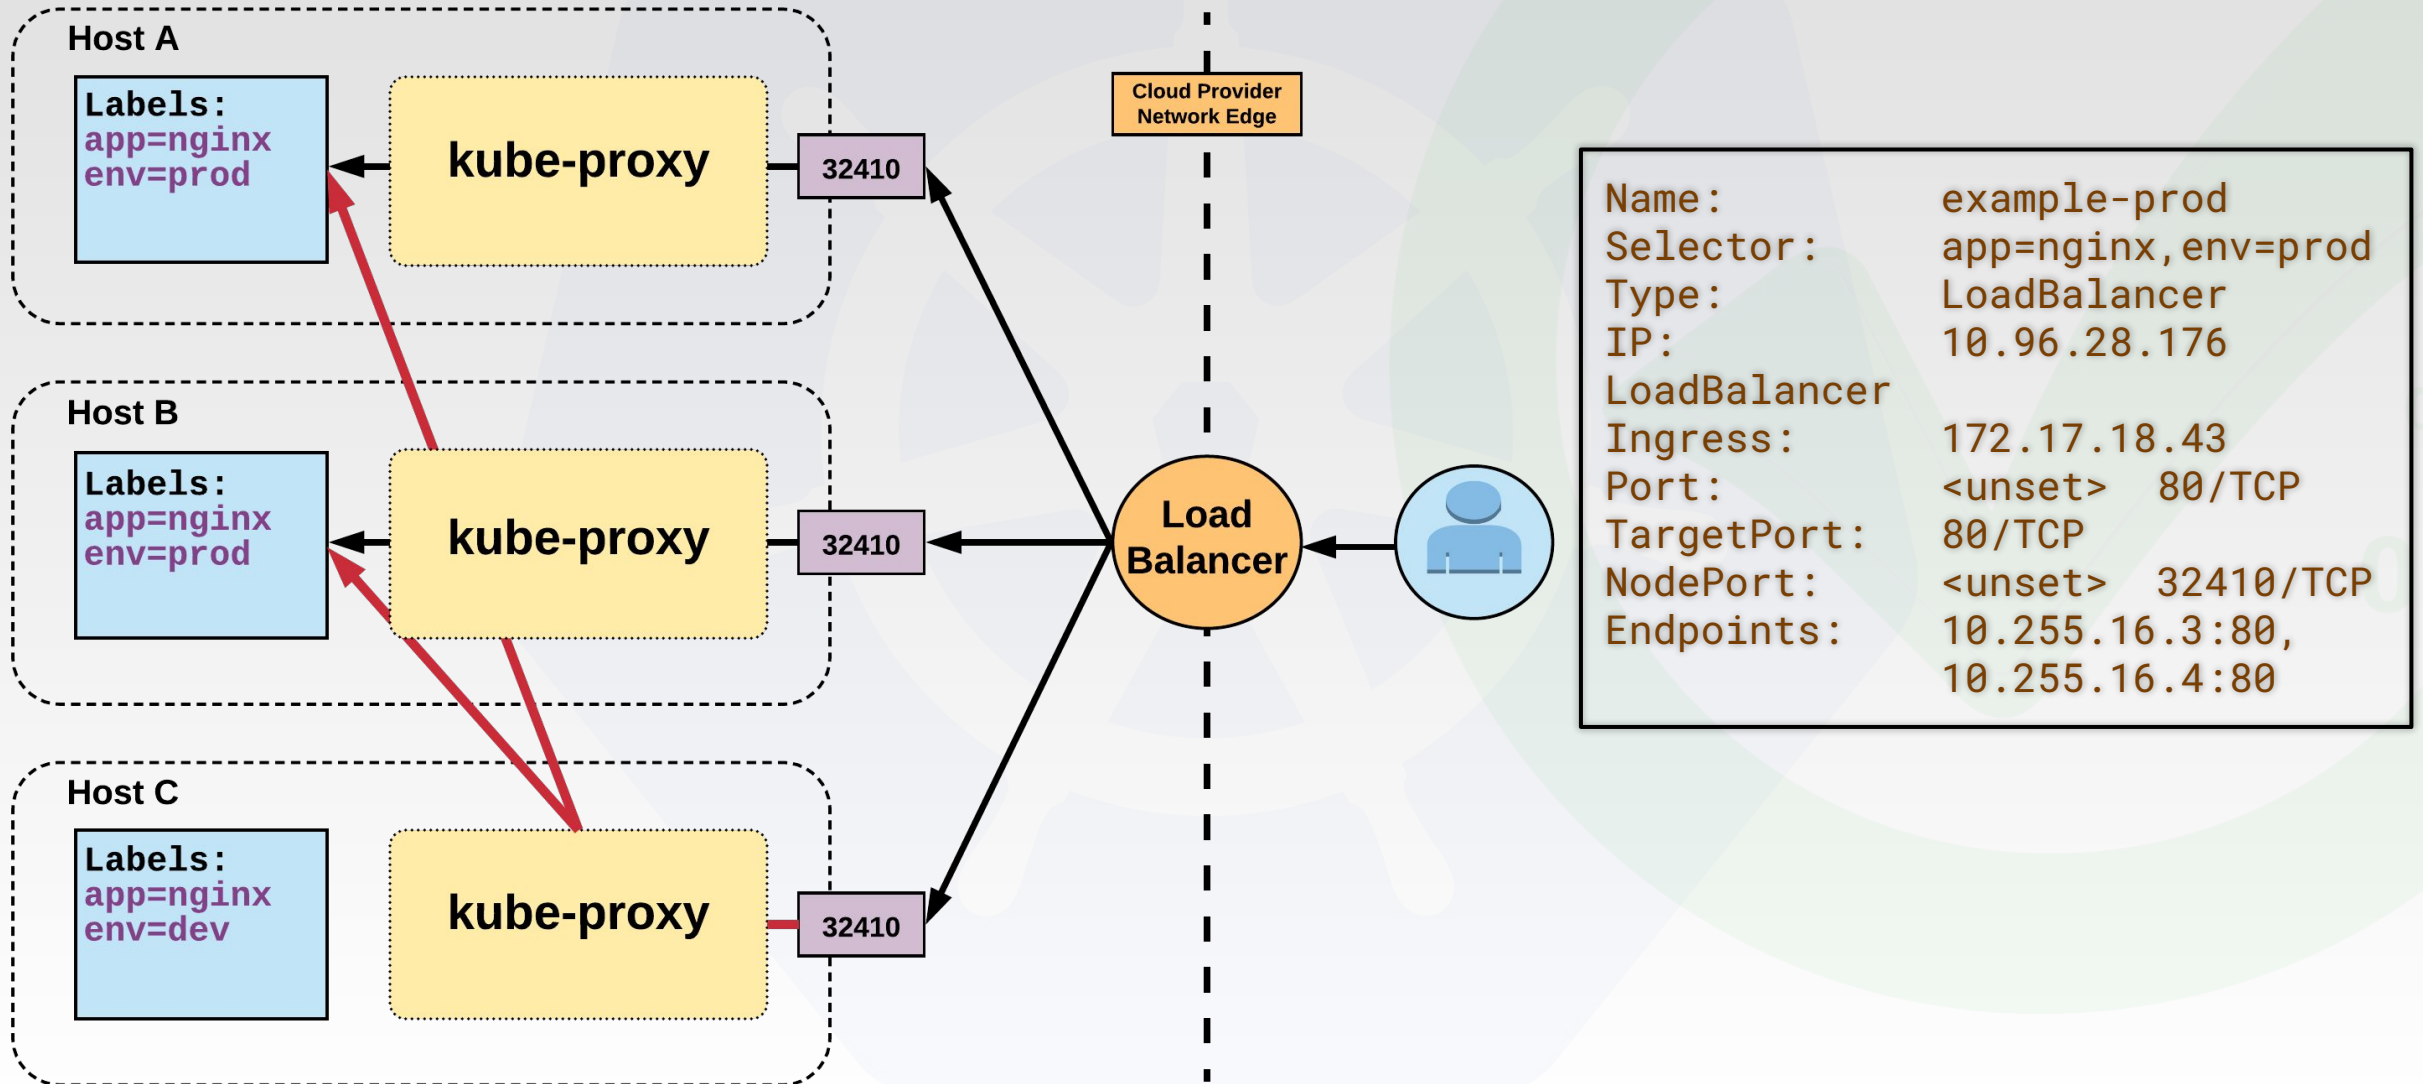

LoadBalancer Service

```
apiVersion: v1
kind: Service
metadata:
  name: example-prod
spec:
  type: LoadBalancer
  selector:
    app: nginx
    env: prod
  ports:
    protocol: TCP
    port: 80
    targetPort: 80
```

- **LoadBalancer** services extend **NodePort**.
- Works in conjunction with an external system (cloud providers) to map a cluster external IP to the exposed service.

LoadBalancer Service

ExternalName Service

- **ExternalName** is used to reference endpoints **OUTSIDE** the cluster.
- Creates an internal **CNAME** DNS entry that aliases another.

```
apiVersion: v1
kind: Service
metadata:
  name: example-prod
spec:
  type: ExternalName
spec:
  externalName: example.com
```

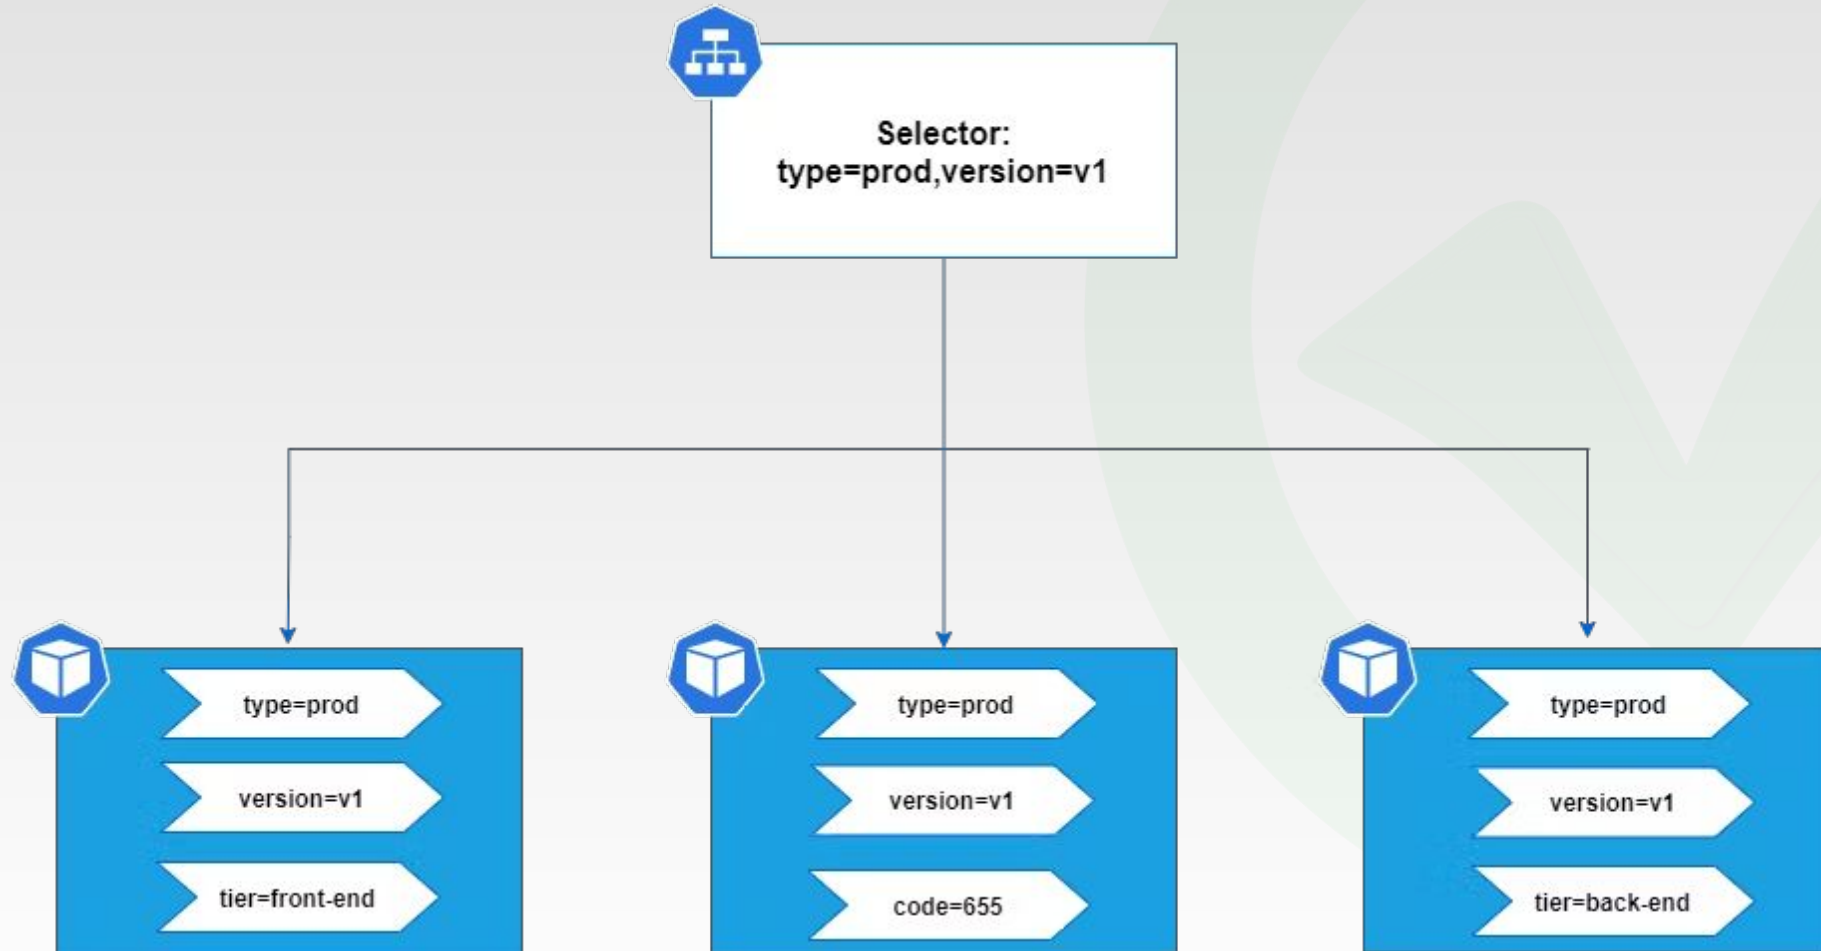

Labels and loose coupling

- Labels and Selectors use a key/value pair format.
- Pods and Services are loosely coupled via labels and label selectors.
- For a Service to match a set of Pods, and therefore provide stable networking and load-balance, it only needs to match some of the Pods labels.
- However, for a Pod to match a Service, the Pod must match all of the values in the Service's label selector.

Labels and loose coupling

Summary

In a K8s cluster:

- For communication inside cluster use service ..
- For traffic coming out of the cluster use ..
- For traffic coming out of the cloud cluster use ..
- For the service to pick up the proper pods use ..

ClusterIP

NodePort

LoadBalancer

Labels, Selectors
